How to read this document

This business plan is the entry point to ZERO Energy: it explains the idea, the problem it addresses and the opportunity, without going into technical detail. Readers who want to go further will find how the protocol works (assets, issuance, staking and governance) in the **Protocol Technical Specification v1.0**.

1

EXECUTIVE SUMMARY

ZERO Energy is a Web3 protocol focused on the tokenization of renewable energy and on building a decentralized green economy, in which every unit of clean energy that is produced and verified can become a traceable digital asset.

The project starts from a simple idea: renewable energy should not only be produced and consumed; it should also be possible to identify it, verify it and prove its origin transparently.

The energy transition is transforming the electricity market. Every year, new solar, wind and other clean generation facilities come online. At the same time, companies, organizations and consumers are increasingly interested in knowing where the electricity they use comes from.

This shift creates a need: systems that can demonstrate that a given amount of renewable energy has actually been produced, and that can record that information reliably.

ZERO Energy proposes to use blockchain technology to meet that need.

Blockchain is a technology for recording information and transactions in a verifiable digital system. Although it is best known for its link to cryptocurrencies, it can also be used to represent assets, certify transactions and keep records.

ZERO Energy applies this technology to the energy sector. Its proposal is to connect renewable production with a digital system that can verify it and represent it through digital energy certificates.

In this way, a real, physical activity (producing clean electricity) can be linked to a digital asset whose record can be identified and followed within the ecosystem.

> **The goal is not to create a cryptocurrency with no connection to the real economy. The goal is to build an energy certification and traceability infrastructure supported by blockchain.**

ZERO Energy also brings in a community organized through a DAO, a governance model in which participants can take part in the decisions set out for the development of the ecosystem.

This combination of renewable energy, digital certification and community participation is the foundation of the project.

The opportunity

The energy market is growing and becoming more digital. The expansion of renewables, the electrification of the economy, the build-out of data centers and the growth of artificial intelligence are all increasing the strategic importance of electricity.

But producing more energy also means generating more information that must be measured, verified and managed. ZERO Energy aims to position itself in that space: the more renewable energy is produced, the greater the potential need for tools that can prove its origin and support its traceability.

The business vision is to develop an ecosystem that connects producers, energy administrators, companies and users around that need.

2

THE PROBLEM WE WANT TO SOLVE

2.1. Producing clean energy is not the same as proving its origin

When a solar installation produces electricity, that energy either flows into the power system or is used directly at the installation itself.

However, once electricity is moving through the grid, it is physically impossible to tell which part comes from a solar installation, a wind farm or any other source of generation.

That is why there are systems for proving the origin of energy through records and certificates. These mechanisms matter because they allow companies and consumers to back up certain claims about the electricity they use.

The challenge is that energy information may be spread across different operators, platforms and procedures. This creates an opportunity for digital solutions that make it easier to record and trace.

2.2. A market that needs transparency

Sustainability has become a relevant issue for companies, institutions and consumers. It is increasingly important to be able to show where the resources used come from and to have verifiable information.

In the energy field, this means being able to answer questions such as:

- Where does the energy come from?
- How much renewable electricity has been produced?
- How has that production been verified?
- Which digital certificate is associated with it?
- What transactions have been carried out with that certificate?

ZERO Energy seeks to make it easier to answer these questions through a digital recording system. The aim is to bring clarity and traceability to the transactions carried out within the protocol.

2.3. Small producers taking part

Renewable electricity generation is no longer the exclusive preserve of large companies. More and more households have solar installations, small businesses produce part of their own electricity and energy communities share renewable projects.

This transformation is creating a more distributed sector with a growing number of participants. However, small producers do not always have the same tools or resources as large operators to manage energy information and certifications.

ZERO Energy envisages a model that can bring in different renewable production profiles, provided they meet the requirements needed to verify their activity. The vision is to help make digital energy certification more accessible and easier to understand.

2.4. The need to connect technology with real utility

For years, much of the public interest in blockchain has focused on buying and selling cryptocurrencies. Yet this technology can also be used to address concrete needs in other sectors.

ZERO Energy builds on that opportunity. Instead of using blockchain only to record movements of digital assets, it proposes linking those records to a physical activity: the production of renewable energy.

In this way, the technology takes on a role connected to a resource that is essential to the economy.

3

OUR SOLUTION: TURNING RENEWABLE ENERGY INTO DIGITAL CERTIFICATES

3.1. An idea that is easy to understand

Imagine a solar installation producing electricity. That installation has systems that measure how much energy it generates.

ZERO Energy proposes that, once that production has been verified, it can be represented by a digital certificate within its ecosystem. That certificate is called ZERO REC (ZREC).

The protocol's energy equivalence is simple:

> **Every 1,000 kilowatt-hours of verified renewable energy, equivalent to 1 megawatt-hour (MWh), allows 1 energy ZREC to be issued.**

The digital certificate makes it possible to represent that amount of energy and to record the transactions carried out with it within the system.

Electricity is still electricity. What is digitized is the certified information about its production. This distinction matters: ZERO Energy does not physically turn electricity into a cryptocurrency; it creates a digital representation of a verified amount of renewable energy.

3.2. How it works in practice

The process can be explained in four steps:

- **First: renewable energy is produced.** A solar, wind or other eligible installation generates electricity.
- **Second: the production is verified.** The system checks the energy information needed to prove the amount produced.
- **Third: the digital certificate is issued.** The verified energy can be represented by energy ZREC.
- **Fourth: the certificate can be used within the ecosystem.** The digital asset has the recording, circulation and retirement functions provided for by the protocol.

All of this makes it possible to connect a real energy activity with a digital traceability system.

3.3. What blockchain brings

Blockchain works as a shared digital ledger in which transactions can be checked. Its usefulness for ZERO Energy comes down to three things:

- **Transparency.** It allows the transactions recorded in the system to be consulted and verified.
- **Traceability.** It makes it easier to follow a certificate's digital history.
- **Automation.** It allows certain operations to be carried out by computer programs called smart contracts.

Not every participant needs to understand how this technology works internally in order to use the ecosystem. Just as a person can use a banking app without knowing its software architecture, the aim is for ZERO Energy's services to be easy for their users to understand.

3.4. What a ZREC represents

ZERO REC (ZREC) is the energy utility digital asset of the ZERO Energy protocol. In its application to energy certification, it digitally represents verified renewable energy production: every 1 MWh (1,000 kWh) of certified renewable energy is equivalent to 1 energy ZREC.

Its role is to support the tokenization, recording and traceability of renewable energy within the ZERO Energy ecosystem.

That is why this document speaks of **energy ZREC**: in the protocol's initial phase, ZREC is also issued from the presale and from community merits, and that ZREC does not represent energy produced. The Technical Specification explains where each one comes from.

3.5. Its value for the market

ZERO Energy's proposal may be of interest to different participants:

- For a **renewable producer**, it offers the possibility of bringing its verified production into a digital certification system.
- For a **company**, it can provide tools to consult and manage information on energy attributes.
- For **ecosystem participants**, it makes it possible to interact with digital assets tied to specific functions.
- For the **community**, it creates an activity linked to energy production that can become part of the protocol's development.

The business idea is for all of these participants to find value in the same infrastructure.

4

PROOF OF ENERGY: A NEW WAY OF UNDERSTANDING THE RELATIONSHIP BETWEEN ENERGY AND BLOCKCHAIN

4.1. What Proof of Energy is

ZERO Energy uses the concept of Proof of Energy (PoE) to describe its model for verifying renewable production. Its principle is simple:

> **Renewable energy must have been produced and verified before it can be represented as energy ZREC.**

Proof of Energy connects the measurement of electricity with its digital certification. The aim is to recognize a real energy activity through a verifiable record.

In the initial stage, that verification is carried out by ZERO Energy. Opening it up to independent validators is part of the protocol's progressive decentralization.

4.2. How it differs from other models

Bitcoin uses a system known as Proof of Work (PoW). In this model, specialized computers continuously perform calculations to take part in securing their network. This process requires large amounts of electricity and can have a significant environmental impact and produce polluting emissions, especially when the energy used comes from fossil fuels.

ZERO Energy proposes a completely different approach. Instead of consuming large amounts of electricity to carry out computational mining, it uses Proof of Energy (PoE) to verify renewable energy that has already been produced and to represent it through digital assets.

The difference between the three models can be summed up as follows:

- **Bitcoin (Proof of Work):** uses computational work and high electricity consumption to secure its network, with an environmental impact that depends on the energy sources used.
- **Helium (Proof of Coverage):** verifies that physical devices installed by its participants genuinely provide connectivity coverage in a given location.
- **ZERO Energy (Proof of Energy):** verifies the production of renewable energy and allows it to be turned into traceable digital certificates, with no need for computational mining.

In this way, ZERO Energy puts forward a use of blockchain directly linked to the production of clean energy and to sustainability.

> **Proof of Energy is not a consensus mechanism and does not replace the security of a blockchain. ZERO Energy uses the Base network to record its transactions, while PoE performs the energy verification function.**

4.3. Helium and ZERO Energy: the potential of the DePIN model

Helium is one of the best-known examples of how blockchain technology can connect with physical infrastructure to create a digital economy.

Its model falls under the DePIN concept (Decentralized Physical Infrastructure Networks). The idea behind DePIN is to connect real-world infrastructure and services with blockchain systems, using digital assets to coordinate participation in, and the operation of, a network.

Helium showed that this model could attract significant interest in the market. Its proposal allowed individuals and businesses to take part in a connectivity network by installing physical devices. These devices helped provide wireless coverage, and their activity was linked to verification mechanisms and digital assets.

The project reached a market capitalization of several billion dollars, becoming one of the benchmarks of the Web3 sector. Its trajectory showed that connecting physical infrastructure, community participation and blockchain could give rise to far-reaching ecosystems.

ZERO Energy shares the same DePIN vision, but applies it to a different sector: renewable energy. While Helium connects telecommunications infrastructure with blockchain, ZERO Energy proposes to connect renewable production facilities with an energy certification and traceability system.

The difference is particularly interesting from a business point of view. Helium needed participants to install specific devices to contribute to its network. ZERO Energy can make use of renewable generation facilities that already exist and are already producing electricity.

Millions of households, businesses and energy facilities have solar panels and other renewable technologies. This represents a potential base of physical infrastructure that does not need to be built from scratch in order to start producing energy. Although bringing it into ZERO Energy will require meeting the protocol's measurement and verification conditions, the generation infrastructure is already in place in many markets.

This feature opens up several opportunities:

- **Existing infrastructure:** ZERO Energy can address producers who already have renewable installations, without necessarily requiring them to buy new generation equipment.
- **A broad and diverse market:** the sector ranges from small self-consumption systems to large solar and wind facilities.
- **A growing need:** the more renewable energy is produced, the more relevant it becomes to have tools that can verify it and prove its origin.

- **Value linked to an essential activity:** electricity is needed by households, businesses, industry and new technologies.
- **Potential for international expansion:** renewable production and the need for energy traceability exist in many countries.

In addition, ZERO Energy is being developed against a backdrop of growth in renewable energy and in electricity demand, which Chapter 7 discusses.

> **ZERO Energy's main differentiating opportunity is that it does not need to create energy production: it seeks to connect and certify an activity that already exists and keeps expanding.**

Helium is therefore a useful benchmark for understanding the potential of the DePIN model. ZERO Energy aims to apply that approach to the renewable energy sector, with a proposal centered on the verification, certification and traceability of its production. Both projects share the connection between physical infrastructure and the digital economy, but they operate in different markets and with different needs.

The size of the energy sector and the existence of millions of renewable installations give ZERO Energy a considerable development opportunity, although making the most of it will depend on the implementation of the protocol, the onboarding of producers and the effective adoption of its services.

If Helium helped show that blockchain could connect with physical telecommunications networks, ZERO Energy aspires to show its usefulness in one of the most important sectors for the future: renewable energy.

4.4. Why this approach matters

ZERO Energy's proposal aims to change the way the usefulness of blockchain is explained. Instead of starting with the price of a digital asset, it starts with a verifiable activity:

- First, there is energy production.
- Then it is checked.
- Finally, it is represented digitally.

This sequence makes it possible to explain the project without any prior knowledge of cryptocurrencies. It also draws a fundamental line between the business model and speculation on digital assets.

> **The core of ZERO Energy is the certification and traceability of renewable energy.**

5

ZERO ENERGY'S BUSINESS MODEL

5.1. An infrastructure that connects different participants

ZERO Energy proposes to develop an ecosystem involving several profiles related to energy and the digital economy. Each one plays a different role:

- **Producers** generate renewable electricity.
- **Energy administrators** take part in the processes needed to certify it.
- The **protocol** makes it possible to represent verified production digitally.
- **Companies and users** can use the services and assets available within the ecosystem.
- The **DAO** takes part in governance and community development.

The business opportunity comes from connecting these activities through a shared infrastructure.

5.2. The energy producer

The producer is whoever owns an installation that generates renewable electricity. It may be a solar installation, a wind installation or another source accepted by the system.

Their activity is the starting point. Without verifiable energy production there can be no issuance of energy ZREC. The growth of certification activity therefore depends on bringing in real production.

5.3. The energy administrator

The energy administrator plays a role in the certification process provided for by the protocol. Their participation connects production activity with the digital recording system.

The model provides that the energy ZREC issued is split between the energy administrator and the DAO treasury. This structure links certification activity with the development of the ecosystem. The details of that split and of the operational functions are set out in the Technical Specification.

5.4. Companies and organizations

Many organizations need to manage information on the origin of energy. ZERO Energy aspires to offer digital tools related to that need. Its proposal may be relevant for companies interested in consulting energy records, managing digital certificates and having traceable information.

In an initial stage, selling certificates to companies is not envisaged. The use of certificates will begin with a voluntary, symbolic pilot involving the community and producers, to show that the model works. Access for companies is a later objective, with no set date and no guarantee.

The use of these records in external environmental claims must comply with the applicable requirements. Neither ZREC nor its digital certificate is equivalent to a Guarantee of Origin, an I-REC, a carbon credit or any other regulated certificate, unless the corresponding integration and accreditation exist. The commercial proposal must be based on the real usefulness of the services, not on automatically attributing to the certificates recognitions that do not apply to them.

5.5. The ZERO Energy community

The community is an important part of the model. ZERO Energy is not conceived simply as a technology platform run by a company: its structure includes a DAO, an organization that makes it possible to develop community participation mechanisms.

The community can take part in the decisions provided for by the protocol and contribute to its evolution. This connects the economic workings of the project with a participatory governance model.

5.6. The ecosystem's digital assets

ZERO Energy uses digital assets with distinct functions:

- **ZERO REC (ZREC)** relates to energy utility and the ecosystem's certification functions.
- **ZERO DAO (ZDAO)** relates to governance and incentives.
- During the presale there is also **TOKEN ZERO**, which represents a right to future minting and not a ZDAO asset that has already been issued.

The role of these elements is to allow the system to organize different activities. It is not necessary to know all their details to understand the business model.

> **Digital assets are tools of the ecosystem, not the ultimate purpose of the project.**

5.7. How activity is generated within the system

The model starts from bringing in verifiable renewable production. That production allows energy ZREC to be issued, and the certificates can be used within the functions provided for by the protocol. The activity of participants, the use of services and the evolution of the community are all part of the ecosystem's development.

ZERO Energy also envisages internal mechanisms for exchange, staking and certificate retirement. These mechanisms broaden the ways in which digital assets can be used.

However, the development of an active ecosystem will depend on the real adoption of its services. The existence of a digital asset does not, on its own, guarantee demand, revenue or economic results.

5.8. What makes the business proposal sustainable

The sustainability of the model must rest on the usefulness of energy certification. This will require developing a reliable infrastructure, bringing in participants and providing services that meet real needs.

The key factors are:

- Renewable production that can be verified.
- Reliable measurement and validation systems.
- Digital tools that are easy to understand.
- The participation of energy administrators.
- Usefulness for companies and users.
- Governance and operational continuity.

The growth of the project will depend on the ability to connect these elements.

6

WHO ZERO ENERGY IS FOR

6.1. Renewable energy producers

The first group of interest is made up of those who produce renewable electricity. It includes both larger installations and smaller-scale producers that can meet the system's technical requirements.

For this segment, ZERO Energy offers a way to represent verified production digitally. The possibility of bringing in installations will depend on the operational procedures available at each stage.

6.2. Energy administrators and operators

Energy administrators are essential to connect the physical world with the digital system. Their activity makes it possible to carry out the planned certification processes.

Collaboration with specialized participants from the sector will be important for the credibility and operation of the protocol.

6.3. Companies committed to energy traceability

Companies that want to know the origin of the energy they use are another potential audience. The growing importance of environmental information makes recording and verification tools relevant for many sectors.

ZERO Energy intends to provide digital solutions related to this need, as an objective for a stage after the initial pilot.

6.4. Energy communities and small producers

Self-consumption and energy communities are broadening participation in renewable generation. These models represent a development opportunity for certification tools adapted to distributed production.

ZERO Energy includes this area in its vision. During the presale phase, however, installations cannot yet be connected and microproducers cannot yet be registered.

6.5. Users interested in technology with real utility

ZERO Energy is also aimed at people who want to understand and take part in Web3 applications related to real-world activities. They do not need any prior knowledge of blockchain technology.

The proposal can be explained through one easy-to-grasp idea:

> **Verify renewable energy and record that information digitally.**

The rest of the ecosystem's tools are built around that function.

7

MARKET OPPORTUNITY AND GROWTH CONTEXT

7.1. The energy transition

The transition to renewable sources is one of the great processes of economic and technological transformation. New solar, wind and other installations are changing the structure of electricity generation.

This growth brings new needs for measurement, data management and certification. ZERO Energy seeks to take part in this process from a specific position: the digital infrastructure for energy traceability.

7.2. The digitalization of the power sector

The energy sector increasingly relies on digital systems to measure and manage production and consumption. Smart meters, monitoring platforms and analytics systems make more detailed information available.

This evolution supports the development of services based on energy data. ZERO Energy proposes to bring in blockchain as a complementary tool for recording certain certificates and transactions.

7.3. Demand for environmental information

Companies, institutions and consumers are increasingly interested in where energy comes from. The need to back up environmental claims makes reliable data more important.

Certification and traceability are essential to avoid confusion and improve transparency. ZERO Energy intends to offer an infrastructure related to these functions.

7.4. Artificial intelligence and the growth of electricity consumption

Artificial intelligence is transforming many economic activities. Its development requires data centers able to process huge amounts of information, and those facilities need electricity to power their equipment and keep their systems running.

According to the International Energy Agency (*Energy and AI* report, April 2025), data centers consumed around 415 terawatt-hours (TWh) in 2024, about 1.5% of the world's electricity, and their consumption could more than double to around 945 TWh by 2030 in its base case. Artificial intelligence is the main driver of that increase: the Agency expects electricity demand from AI-

optimized data centers to more than quadruple over the same period. These projections carry a wide margin of uncertainty, and they refer to data center consumption, not to global electricity demand as a whole.

This phenomenon adds to other trends, such as the electrification of transport, industry and heating and cooling. As a result, the availability of energy is becoming an increasingly important factor for technological development, and the relevance of renewable sources and of systems able to prove their production is growing too.

For ZERO Energy, this trend reinforces the market opportunity: the growth of renewable production can broaden the need for energy certification and traceability.

The project does not aim to meet the electricity demand of artificial intelligence directly. Its current role is different: developing tools to verify renewable energy and represent it digitally.

7.5. An opportunity tied to the real economy

ZERO Energy's opportunity does not depend solely on the growth of Web3. It is tied to an essential economic activity: the production and management of electricity.

The energy sector will continue to need systems for measuring, reporting and proving the origin of its resources. The proposal is to add a new digital infrastructure to that environment. Its adoption will depend on its being useful to participants and on its ability to integrate with the relevant procedures.

8

VISION, MISSION AND VALUES

8.1. Our vision

ZERO Energy's vision is to contribute to the development of a decentralized green economy in which renewable production can be represented through verifiable digital assets.

The project aspires to connect energy, technology and community. The aim is for blockchain to have an application that is easy to understand and linked to real needs. ZERO Energy wants energy tokenization to become part of a new generation of digital services focused on sustainability.

8.2. Our mission

ZERO Energy's mission is to develop a Web3 infrastructure that makes it possible to verify, tokenize and support the traceability of renewable energy production.

To do so, the project seeks to connect producers, energy administrators, organizations and users through a shared ecosystem. Its purpose is to make digital energy certification tools more accessible and to promote community governance.

8.3. Transparency

Transparency is one of the model's principles. The use of blockchain makes it possible to record verifiable transactions within the ecosystem.

Information must be presented clearly, distinguishing what has been implemented from what belongs to future stages. It is also important to distinguish the protocol's own certificates from external recognition systems.

8.4. Real utility

ZERO Energy starts from the idea that technology should respond to concrete needs. That is why the project focuses on verifiable energy production.

Blockchain is a tool. Energy certification and traceability are its main application.

8.5. Community participation

The DAO holds a central place in the organizational vision. The aim is for the community to be able to take part in the governance mechanisms provided for. This approach seeks to connect the evolution of the ecosystem with transparent decision-making procedures.

8.6. Sustainability

ZERO Energy directs its activity toward renewable energy and the traceability of its attributes. The project does not replace the physical production of electricity, nor does it automatically turn every digital transaction into an emissions reduction.

Its potential contribution lies in providing verifiable information and certification tools.

8.7. Accessibility

The proposal must be understandable without advanced knowledge of blockchain. The technology may be complex internally, but its usefulness must be explained clearly.

ZERO Energy aspires to bring energy tokenization closer to producers, companies and users through concepts that are easy to grasp.

9

PROJECT DEVELOPMENT AND FUTURE OUTLOOK

9.1. A step-by-step evolution

ZERO Energy is a project under development. Its growth requires implementing technological tools, establishing verification processes and bringing in participants from the energy sector.

The current phase corresponds to the presale and to the development work that precedes the launch of the protocol's components. No smart contracts have been deployed yet. It is therefore important to distinguish between the planned architecture and the services that are already available.

9.2. The presale phase

During the presale, TOKEN ZERO is acquired. It represents a right to future minting that will be settled according to the protocol's conditions: at the Claim, each participant chooses to convert it into ZERO DAO (ZDAO) or ZERO REC (ZREC). It does not mean that the participant is directly acquiring ZDAO that has already been issued.

The presale is a preparation stage for the ecosystem. In this phase, energy installations cannot yet be connected and microproducers cannot yet be registered.

9.3. The planned launch

The token launch (TGE, *Token Generation Event*) is planned for December 31, 2027, at 23:59 UTC. It opens the Claim period, in which presale participants exercise their minting right.

The specific conditions of the assets and the associated procedures are set out in the Technical Specification.

9.4. Consolidating energy activity

The business priority is to develop the energy certification and traceability system. This requires the technological infrastructure to work properly and participants able to contribute verifiable renewable production to be brought in.

The growth of the project should be measured by its real activity. The most relevant indicators will include the onboarding of energy production, the issuance of certificates and the effective use of services.

9.5. A possible second stage: tokenizing renewable infrastructure

Beyond the current energy certification activity, there is a possible line of expansion that could be studied in the future: exploring the tokenization of physical renewable generation infrastructure, such as solar parks.

In general terms, tokenizing infrastructure means studying how certain rights or forms of participation linked to a physical asset could be represented through digital tools. Applied to the renewable sector, this idea could open the door to collective or cooperative models related to power generation facilities.

However, it is essential to keep the two concepts separate. ZERO Energy's current model consists of certifying renewable energy that has been produced and making it traceable. The possible tokenization of solar parks would be a different line of business, not yet defined or approved.

> **There are currently no official conditions of participation, ownership, financing or operation associated with this possibility. Developing it would require specific technical, legal and economic studies. It should be understood solely as a long-term expansion vision, not as a current feature or commitment of the protocol.**

10

CONCLUSION: THE FUTURE OF DIGITAL ENERGY CERTIFICATION

ZERO Energy is born from the meeting of two transformations. On the one hand, the growth of renewable production and the need for reliable information about its origin. On the other, the evolution of digital technologies that make it possible to record, verify and manage assets in new ways.

The project connects both trends through a simple proposal:

> **Use blockchain to certify verified renewable energy and support its traceability.**

Its main activity is not producing electricity, but developing a digital infrastructure related to proving its origin:

- Renewable production is the source of the information.
- Proof of Energy makes it possible to verify it.
- ZERO REC makes it possible to represent it digitally.
- Blockchain supports its recording and traceability.
- The DAO brings in a community governance model.

Together, these elements form an ecosystem that seeks to bring value to producers, energy administrators, companies and users.

The market opportunity is linked to the expansion of renewable energy and the growing need to manage energy information transparently. The growth of electricity demand, driven by electrification and new technologies such as artificial intelligence, reinforces the strategic importance of this sector. But ZERO Energy's opportunity does not depend on producing that electricity: it depends on developing useful tools to verify it and prove its origin.

The project is at a development stage, and consolidating it will require technological implementation, energy integration and real adoption. The priority is to build a solid certification and traceability infrastructure. Possible future opportunities, such as the tokenization of solar parks, remain separate from this core activity.

ZERO Energy aspires to show that blockchain technology can have concrete usefulness in the real economy and contribute to greater transparency in the renewable energy sector.
